3. Advanced Mode Walkthrough

4. The Intent Block System

5. Tips

A complete walkthrough of the Benchmark Wizard — from workload description to live results.

1. Overview

The Benchmark Wizard transforms a description of your AI workload into a reproducible benchmark plan. It operates in two modes:

- **Simple mode** (default): Natural language input, streamlined steps, minimal decisions. Best for getting started quickly.
- **Advanced mode**: Structured questionnaire with full control over every parameter. Best for experienced evaluators who need granular configuration.

Toggle between modes using the **Simple / Advanced** switch at the top of the wizard. Your choice persists across sessions.

In both modes, the wizard now combines intent classification and model selection into a single first step — the disciplines you select drive the model match scoring you see right next to them.

2. Simple Mode Walkthrough

Step 1: Tell Us What You Need (Intent & Model Selection)

Type a natural language description of what the AI model needs to handle:

"I need a model that can review pull requests, suggest code improvements, and explain complex functions to junior developers."

The wizard sends your description to a two-stage classifier that:

1. Categorizes your intent (e.g., software, reasoning, safety, agentic).
2. Selects disciplines — specific evaluation areas within those categories, ranked by relevance.

The result appears as selectable discipline tags. Each tag shows the discipline name, test count, and estimated run time.

Models appear in the same step. All models from all configured providers are listed in a unified panel beside the disciplines. Each model card shows:

- Model name and provider
- Parameter count and context window
- **Match percentage** — how relevant this model is to your selected disciplines (green > 70%, yellow 40–70%, red < 40%)
- VRAM fit indicator (green = fits, yellow = tight, red = too large)
- A **Get** button for catalog models you don't yet have installed

Select one or more models by checking their boxes. The bundled quick-start model and any locally running models (Ollama, LM Studio) are always available. Cloud models appear if you've configured API keys.

Confidence framing. The wizard is transparent about how well it understood your request:

- *High confidence*: "Based on your description, Code Generation is a strong match — it tests whether the model can produce correct, idiomatic code from natural language prompts."
- *Medium confidence*: "My best guess is Code Debugging, though Code Review could also fit. Do any of these look right?"
- *Low confidence*: "I wasn't confident enough to recommend specific tests. Could you tell me more about what the model will actually be doing day-to-day?"

You can add or remove disciplines manually regardless of the classifier's suggestions.

Step 2: Select Tests

Review the tests that will run based on your selected disciplines. The plan is auto-assembled in Simple mode. You see:

- Tests grouped by domain
- Total test count and estimated runtime
- Coverage warnings if a discipline has thin test coverage

Step 3: Review & Queue

Confirm session name, contact name, and run parameters. Select a pre-built test suite if you don't want to use the auto-assembled plan. For cloud models, the cost estimate appears here — a confirmation dialog shows if it exceeds your warning threshold.

Click **Create & Enqueue** to submit the benchmark to the execution queue.

Step 4: Watch Progress

The live execution screen displays test progress, pass/fail counters, GPU telemetry, and an activity log. Thermal protection is always active: benchmarks pause at 80°C and abort at 95°C.

Step 5: View Results

Click **View Full Results** when execution completes to see the composite Score, per-domain breakdowns, and individual test results.

3. Advanced Mode Walkthrough

Advanced mode replaces the natural language input with a structured questionnaire and adds fine-grained control over the test plan.

Step 1: Structured Intent + Model Selection

Instead of free-text input, fill out a detailed form:

Field	Options
Primary Intent Type	General, Code, Reasoning, Vision, Agentic, Writing
Output Requirements	Structured JSON, Tool Calling, Code Generation, Multimodal Input, Long Context, High Accuracy
Context Bucket	Short (<4K tokens), Medium (4K–16K), Long (16K–64K), Very Long (64K+)
Deployment Constraints	Local Only, Cloud Only, Privacy Sensitive, Budget Friendly, Open Source Preferred
Latency Priority	Speed, Balanced, Quality
Target Hardware	This system (auto-detected) or different system (manual VRAM/budget entry)

Quick Picks — eight pre-assembled configurations for common use cases (Document Q&A, Code Review, Safety Evaluation, etc.) that fill in the form with a single click.

The same unified model list as Simple mode appears alongside the questionnaire, but here models are scored against your full questionnaire answers, not just discipline matches.

Step 2: Select Tests — Suite & Discipline Customization

Browse all 22 pre-built test suites. Each suite shows:

- Name, description, and category
- Test count and estimated duration
- Tier requirement (Trial or Pro+)
- Last run date (if previously used)

Select a suite, or let the wizard auto-assemble a plan from your questionnaire responses using the intent block system. Then customize individual tests:

- **Weight:** Required, Recommended, or Optional
- **Score weight:** 1.0–2.0 multiplier
- **Contributing block:** Which intent block included this test and why

Toggle individual tests on or off. If a test is excluded by one block but required by another, the conflict is displayed with an explanation of how it was resolved (required wins).

Save as Custom Suite (Consultant tier and above): Save your customized test selection as a reusable suite.

Step 3: Session Configuration

Setting	Description
Session Name	Auto-generated or custom. Appears in results and reports.
Contact Name	Optional. Included in PDF reports.
Deterministic Mode	Lock execution order and disable sampling randomness.
Global Seed	Seed value for deterministic mode.
Temperature Override	Override the model's temperature setting for all tests.
Runtime Target	GPU or CPU. Auto-detected hardware shown for reference.

Step 4: Final Review & Cost Estimate

A summary of every choice: disciplines, suite, tests, models, configuration. For cloud models, the cost estimator shows projected input/output token counts, per-model API cost breakdown, total estimated cost, and confidence level. If the estimated cost exceeds your warning threshold (default \$5), a confirmation dialog appears.

Last chance to go back and adjust before submission.

Step 5: Benchmark Execution

The live execution screen displays:

- Test progress: Current test name, X of Y completed
- Counters: Pass, fail, and anomaly counts
- Elapsed time with running clock
- GPU telemetry (NVIDIA): Temperature gauge (color-coded), GPU load, VRAM usage
- Activity log: Timestamped messages for each test start, completion, and notable event

Controls:

- **Stop** — Cancel the running benchmark
- **View Full Results** — Appears when execution completes

Thermal protection is always active: benchmarks pause at 80°C and abort at 95°C.

4. The Intent Block System

Behind the scenes, the wizard assembles benchmark plans using **intent blocks** — pre-built modules that map capabilities to specific tests.

Each intent block defines:

- **What it proves** — the capabilities being tested
- **Which tests** — drawn from the 254-test library, with weights (required/recommended/optional)
- **Exclusions** — tests that would be misleading for this use case
- **Score weights** — multipliers (1.0–2.0) for test importance

When multiple blocks are combined, the assembly engine:

1. Deduplicates tests, keeping the highest weight
2. Merges score weights (capped at 2.0)
3. Resolves conflicts between blocks (required always wins over excluded)
4. Generates an audit trail showing which block contributed each test

This system ensures that benchmark plans are repeatable, explainable, and grounded in real test coverage — not guesswork.

5. Tips

- **Start with Simple mode.** Switch to Advanced only when you need fine-grained control.
- **Be specific in your description.** "Answer customer questions from our knowledge base" produces better matches than "general chatbot."
- **Check discipline coverage.** If a discipline shows a "thin coverage" warning, results will be directional rather than definitive.
- **Run multiple models.** The real value of benchmarking comes from comparing models side by side.
